

## BIO SPECTRA QUESTIONNAIRE FOR EXCIPIENT NITROSAMINES RISK EVALUATION

On September 19<sup>th</sup>, 2019, European Medicines Agency (EMA) published a new requirement that Marketing Authorization Holders (MAHs) for human medicines containing chemically synthesized active substances review their medicines for the possible presence of nitrosamines.

1. Information on nitrosamines for marketing authorization holders (EMA/189634/2019)<sup>1</sup>
2. Questions and answers on “Information on nitrosamines for marketing authorization holders” (EMA/CHMP/428592/2019 Rev. 1)<sup>2</sup>

Other authorities started an equivalent approach, e.g. Health Canada<sup>3</sup>, TGA (Australia), Swissmedic<sup>4</sup>.

In September 2020, the US Food and Drug Administration (US FDA) published a guidance for the Control of Nitrosamine Impurities in Human Drugs<sup>5</sup>.

This questionnaire was developed with reference to EMA requirements on this topic. However, the information generated should also assist companies to address similar requests from other regulatory authorities, based on our current understanding of global activity on this subject.

The use of a standard format will facilitate data collection from excipient suppliers and thus enable a more efficient process of conducting the required risk assessments by drug product manufacturers / Marketing Authorisation Holders.

Information for nitrosamine risk evaluation is provided to the best of our knowledge, considering available supplier information and likely chemical production processes where information from the supplier is not available.

This information for nitrosamine risk evaluation is prepared for:

Product Name:	Tris Hydrochloride, Bio Excipient Grade and Bio Pharma Grade
Product CAS Number:	1185-53-1
Supplier:	BioSpectra, Inc.
Supplier Contact Name: <i>(Please print full name)</i>	Cassie Baun
Supplier Signature:	<i>Cassie Baun</i>
Date Completed:	10/5/22

**Annex**<sup>11</sup>:

### **Guidance 1 (Sources of nitrosating agents)**

Nitrosating agents to be considered include; nitrites (e.g. sodium nitrite, NaNO<sub>2</sub>) and nitrous acid (HNO<sub>2</sub>), nitric oxide (NO), nitrosyl halides (e.g. ClNO, BrNO), dinitrogen trioxide (N<sub>2</sub>O<sub>3</sub>), dinitrogen tetroxide (N<sub>2</sub>O<sub>4</sub>) and organic nitrites (e.g. t-BuONO).

Other potential nitrosation risks:

- Side reaction in nitration reactions. Nitric acid typically contains nitric oxide as an impurity, additional nitrous acid may also be produced, leading to nitrosation, if any reducing agents are present.
- Hydroxylamine under oxidative conditions
- Chloramines are known to generate N-nitrosamines under certain conditions and so should also be considered<sup>12</sup>
- Ozone may lead to the formation of N-nitrosamines by initial oxidation of amines to nitrite<sup>9</sup>
- Use of azide salts and azide compounds is commonly followed by quenching with nitrous acid or nitrites and may lead to nitrite residues.<sup>1</sup>
- Nitric acid and nitrates under reducing conditions may result in by-products with nitrosating activity.<sup>10</sup>

This evaluation must include the use of all chemicals within a process, including those used during the quench and work-up as well as during reactive chemistry.

### **Guidance 2 (Sources of secondary and tertiary amines)**<sup>13</sup>

Secondary amines are of greatest concern, however tertiary amines can also undergo nitrosation via more complex pathways. All secondary and tertiary aliphatic and aromatic amines should therefore be considered including those present as part of the starting material, intermediate or final structure as well as those introduced as reagents, catalysts, solvents or as impurities.

Tertiary amine bases (i.e. triethylamine, diisopropylethylamine and N-methylmorpholine) are known to degrade to secondary amines and have been implicated in N-nitrosamine formation.

Amines may also be introduced as impurities or degradants:

- Of common amide containing solvents such as N,N-dimethylformamide (DMF), N,N-dimethylacetamide (DMAC) and N-methylpyrrolidinone (NMP)
- Of quaternary ammonium salts such as tetrabutylammonium bromide (TBAB)
- Of primary amines such as monoethylamine
- Of starting materials, intermediates or the product itself

This evaluation must include the use of all chemicals within a process, including those used during the quench and work-up as well as during reactive chemistry.

### **Guidance 3 (Potential contamination risks)**

Product Code: Reference the Tris Hydrochloride Bangor Manufactured Compliance Statements Cover Letter

Product Name: Tris Hydrochloride, Bio Excipient Grade and Bio Pharma Grade

Consider all potential sources of contamination in input materials

Use of recovered materials (solvents, reagents, catalysts) is of particular concern if appropriate controls are not put in place. The materials DMF, ortho-xylene and tributyltin chloride were highlighted by the EMA as materials at risk of cross contamination by N-nitrosamines. Sodium azide was highlighted by Health Canada for risk of cross contamination with nitrite.

Cross contamination from other processes using shared equipment should be considered. Steps performed under GMP (using solvents/reagents with appropriate controls, and controls on their recovery and reuse) are considered to be a lower cross contamination risk.

#### **Guidance 4 (Determining an acceptable level)**

Interim acceptable daily intakes for chronic exposure to several common N-nitrosamines have been defined. See literature reference<sup>14</sup> for EMA interim acceptable daily intake for chronic exposure to common N-nitrosamines.

Processes to determine acceptable intakes for all other N-nitrosamines should be in alignment with the EFPIA paper.<sup>15</sup>

These levels should be adjusted for less than lifetime exposures as described in ICH M7.<sup>16</sup>

Calculate acceptable limits in ppm relative to the substance using the maximum daily dose. Higher limits may be justified for ICH S9 indications.<sup>17</sup>

#### **Guidance 5 (Conducting purge assessments)**<sup>18</sup>

Where a nitrosating agent and amine have the potential to be concurrently present an assessment of the process conditions should be conducted to determine if a N-nitrosamine could potentially be formed and what the maximum realistic level could be. Nitrosation occurs more rapidly under acidic conditions (apart from organic nitrites) and may also be catalysed by certain anions and aldehydes (notably thiocyanate and formaldehyde).<sup>10,19</sup>

During purge calculations consider the likely physicochemical characteristics of the N-nitrosamine which may be formed. For instance, NDMA has a BP of 153°C and will partition in both aqueous and organic layers. It is highly soluble in water and organic solvents. Other, higher molecular weight, N-nitrosamines will behave differently.

N-nitrosamines are relatively stable compounds though the following conditions are known to result in de-nitrosation:

- Strongly acidic condition with a nucleophile trap (e.g. HCl with MeOH)
- Metal reducing conditions (e.g. Zn AcOH; Ni/Al KOH)
- Pd/C Hydrogenation
- Grignards
